CareBrief

Bring your questions. Leave with a clearer record.

THE PROBLEM

People can arrive at an appointment with questions scattered across memory and notes. CareBrief explores a simple way to prepare an agenda and keep a clear record of questions discussed. This is a product hypothesis; no patient research or clinical outcomes are claimed.

THE WORKING PROTOTYPE

Enter a visit label and date, add questions with two priority levels, mark questions discussed, and record notes. The brief separates pending questions from those marked discussed, copies notes exactly, and supports text download and print/PDF. A fictional administrative example is built in.

IMPLEMENTATION

A single HTML file contains responsive CSS and JavaScript. Questions sort by priority and insertion order. All entered text is rendered as text, not executable HTML. State stays only in page memory and clears on reload. The app has no model inference, application API calls or account requirement.

SOLO ENTRY AND SCOPE

A solo entry by Vivaan Kandhari. This is a deterministic appointment organizer. It does not diagnose, interpret symptoms, recommend treatment or verify appointment outcomes. The entrant must review the code and demonstrate the prototype.

FEASIBILITY AND NEXT STEPS

The static app can run locally without dependencies. Next steps are user feedback on agenda preparation, accessibility checks and an evaluation of whether explicit user-controlled persistence is useful. No deployment, adoption, revenue or clinical validation is claimed.

SUBMISSION MATERIALS

Materials for DSH Hacks V2 and UnivaBio: interactive HTML prototype, complete code PDF, and a narrated demonstration with real app interaction captures. The video uses a synthesized voice and fictional data. Theme acceptance remains the organizer's decision. No clinical validation is claimed.
